

Air Quality Analysis for Lead

The following information is for the ambient air monitors operated by the state, and it is uploaded to EPA's Air Quality System database. The monitoring information provided in the charts below highlights air pollutant levels that are in violation of the National Ambient Air Quality Standards, or NAAQS.

On October 15, 2008, the EPA revised the primary National Ambient Air Quality Standard for airborne lead from 1.5 micrograms per cubic meter, or $\mu\text{g}/\text{m}^3$, to $0.15 \mu\text{g}/\text{m}^3$, calculated as three-month rolling averages.

With the lead standard revision, EPA has required states to install and start operating source-oriented monitors, particularly near sources that annually have more than one ton of lead emissions. These monitors were installed and operating by January 1, 2010. There are now a total of 13 state-operated lead monitoring sites in Missouri.

The following table shows three-month rolling average airborne lead concentrations for the last twelve months, measured at both state and contractor sites. Ambient concentrations that exceed the standard are highlighted in yellow in the table. Lead concentrations in excess of the standard have been measured near the Herculaneum primary lead smelter, near the Buick secondary smelter and near the Forest City secondary smelter. The Air Pollution Control Program is working with the operators of these facilities to reduce lead emissions and bring each of these three areas into compliance with the lead standard. Recent exceedance of the standard at Glover is the result of temporary demolition activity at the Glover facility, which is no longer in operation. Demolition procedures at Glover have been revised to reduce lead emissions.

Preliminary 3-Month Average Lead Concentrations, March 2016-May 2017, micrograms per cubic meter ($\mu\text{g}/\text{m}^3$)

Updated 7/13/2017

Site numbers correspond to map legend.

Blue highlight indicates non-ambient sites, i.e., sites within a facility fence line.
 Yellow highlight indicates exceedance of the NAAQS (3-month average greater than 0.15 $\mu\text{g}/\text{m}^3$).

Samples are collected for 24 hours every sixth day except as noted below.
 EPA's Air Quality System (AQS) does not have a report that will calculate and provide three-month rolling averages for each month.
 The values in this table are calculated from data reported to AQS by the department. These values may differ slightly from subsequent AQS averages if reports of averages become available or from design values (maximum 3-month average in a 3-year period).

*Blair St. measures PM10 lead by a federal equivalent method as part of the NATTS program. Data are received about 2 months later than from other sites.

^Sherman and Dunklin High School sites sample every 3 days. St. Joe State Park site sampled every 3 days through March 2016, then every six days. Averages include all samples.

^^Mott St. site samples every day. Averages include all samples.

**St. Joe State Park collected valid samples on only 2 days out of 5 scheduled in October 2016 and Fletcher collected valid sample on only 1 day out of 5 scheduled in March 2017.

Preliminary 3-month averages above (shown in blue) are therefore based on incomplete data. AQS will calculate final 3-month averages using substitution of earlier data; results may be slightly different.
